# An heuristic implementation for Boolean Satisfiability Problem

# Ian Gabriel, Carlos Eduardo

<sup>1</sup> Federal University of Rio Grande do Norte, Natal, Brazil

**Abstract.** This report mainly presents an heuristic implementation of an algorithm for the satisfiability problem, together with experimental results, while also discussing the current heuristics available for this problem. It is worth mentioning that this is a graded assignment for the discipline of Algorithms Analysis and Projects of the Federal University of Rio Grande do Norte.

### 1. Introduction

The boolean satisfiability problem (SAT) involves determining if a logical formula can be satisfied. Despite its straightforward definition, SAT has several practical applications across several fields. For example, SAT can be used for software and hardware verification, artificial intelligence, and bioinformatics [Marques-Silva 2008]. These diverse applications demonstrate the problem's impact across both theoretical and practical worlds.

SAT has became one of the main problems in the fields of computer science and mathematics. Not only because of its practical applications, but for its high difficulty. SAT is the first problem to be proved NP-complete [Cook 1971]. Therefore, solving SAT proves that P=NP, leading to great advance in the computer science field.

Among many algorithm to solve SAT, we highlight DPLL, which is a backtracking algorithm that uses an heuristic to choose the most promising branch on the search space. This way, the algorithm prunes some branches of the search tree, gaining efficiency.

For this report, we present a modification of DPLL called CIDPLL, which uses another heuristic to decide the best value to assign a variable. Since CIDPLL does not go through all the search space, it can provide incorrect answers. However, CIDPLL has a polynomial worst case complexity, having a faster runtime.

The report is structured as follows: Section 2 defines the SAT problem. Section 3 explains abut DPLL and our modified version CIDPLL. Section 4 show the implementation details of CIDPLL. Section 5 contains the empirical analysis results. Section 6 discuss the results. Finally, Section 7 concludes this report.

# 2. Boolean Satisfability Problem (SAT)

# 2.1. Conjuctive Normal Form (CNF)

A propositional logic formula is said to be in the Conjuctive Normal Form if it has the form:

$$P_1 \wedge P_2 \wedge \cdots \wedge P_n$$

where  $P_i$  is a disjunction of positive or negative literals. Formally,  $P_i$  is written as:

$$Q_1 \vee Q_2 \vee \cdots \vee Q_n$$

and  $Q_i$  is x or  $\neg x$  for a variable x.

An example of CNF formula is:  $(x \lor y \lor \neg z) \land (x \lor \neg y) \land (\neg w \lor x)$ 

### 2.2. SAT problem

The satisfiability problem is defined as follows: Given a CNF formula, return an assignment of the variables such that the formula becomes true, or answer that the formula is unsatisfiable.

More formally, the input is a string which is guaranteed to be a valid CNF formula. The output should be a function  $\alpha: X \to \{0,1\}$  such that the evaluation of the formula from this assignment is 1. Here, X is the set of variables present in the formula. If such function does not exist, answer accordingly.

# 3. DPLL algorithm

Davis-Putnam-Logemann-Loveland (DPLL) is a complete search algorithm for deciding the satisfiability of a CNF formula. It is essentially a backtracking algorithm, designed to work with an heuristic to choose the next variable to be assigned. For this reason, DPLL is considered to be a family of algorithms, since the chosen heuristic can change the algorithm's efficiency.

DPLL is described at Algorithm 1. Here, we define an auxiliary function apply, which receives a formula, a variable and a boolean. This function is responsible returning the reduced formula when the variable is assigned the respective boolean value. Some possible reduction steps the apply function uses are:

- $A \lor 0 = A$
- $A \lor 1 = 1$
- $A \wedge 0 = 0$
- $A \wedge 1 = A$

Moreover, we have the function  $next\_variable$ , which is the heuristic responsible for deciding the next variable to have its value assigned. Additionally, the notation  $\alpha[x \leftarrow v]$  can be read as "the same assignment as  $\alpha$  but the variable x is assigned to value v".

Since a complete algorithm is out of scope, for this work, we present a new algorithm derived from DPLL called CIDPLL (Carlos & Ian DPLL). This algorithm uses another heuristic to decide which is the best value to assign to the next variable. It is a greedy algorithm because after deciding a variable's value, it does not go back. Besides the fact that CIDPLL uses an heuristic to guess the best value to assign a variable, the algorithm is very similar to DPLL. This can be seen at Algorithm 2

# 4. Implementation of CIDPLL

The first requirement to implement CIDPLL is to specify both next\_variable and best\_value heuristics. For the next\_variable heuristic, we are going to use Dynamic Largest Individual Sum (DLIS). For the best\_value, we are going to use our own heuristic called Most Common Literals (MCL).

# **Algorithm 1** DPLL

```
Input: A set of clauses \Phi
Output: A solution to satisfy \Phi
function DPLL(\Phi, \alpha)
   if \Phi has empty clause then return no solution
   end if
   if \Phi has no clauses then return \alpha
    end if
   if \Phi has a clause with exactly one literal l then
        if l = \neg x then return DPLL(apply(\Phi, x, 0), \alpha[x \leftarrow 0])
     return DPLL(apply(\Phi, x, 1), \alpha[x \leftarrow 1])
        end if
    end if
    var \leftarrow next\_variable(\Phi)
     return DPLL(apply(\Phi, var, 0), \alpha[var \leftarrow 0]) or
DPLL(apply(\Phi, var 1), \alpha[var \leftarrow 1])
end function
```

### **Algorithm 2** CIDPLL

```
Input: A set of clauses \Phi
Output: A solution to satisfy \Phi
function DPLL(\Phi, \alpha)
   if \Phi has empty clause then return no solution
   end if
   if \Phi has no clauses then return \alpha
   end if
   if \Phi has a clause with exactly one literal l then
        if l = \neg x then return DPLL(apply(\Phi, x, 0), \alpha[x \leftarrow 0])
     return DPLL(apply(\Phi, x, 1), \alpha[x \leftarrow 1])
        end if
    end if
    var \leftarrow next\_variable(\Phi)
    value \leftarrow best_value(\Phi, var)
     return DPLL(apply(\Phi, var, value), \alpha[var \leftarrow value])
end function
```

#### 4.1. DLIS

DLIS consists of selecting the variable with the most occurrences in the formula. The main goal of this heuristic is to reduce the formula as most as possible. This way, the algorithm reaches a base case faster, reducing execution time.

Our implementation of DLIS consists of iterating for all possible variables and then checking all possible clause sizes. For each clause size, iterate all clauses of that size and count the current variable occurrences. This process can be seen at Algorithm 3

### **Algorithm 3** DLIS

```
Input: \Phi a clause set
Output: The variable with most occurrences in \Phi
function DLIS(\Phi)
    best: Var
    \max \leftarrow -\infty
    for x in \Phi. Variables do
         count \leftarrow 0
         k \leftarrow \Phi.Biggest\_Clause\_Size()
         for i in [1 . . . k] do
             for c in \Phi.Clauses_With_Size(i) do count \leftarrow count + occurrences(c, x)
             end for
         end for
         if count > max then
             \mathsf{best} \leftarrow x
             max \leftarrow count
         end if
    end for
      return best
end function
```

Assuming that  $\Phi$  is always reduced, we can infer that the size of each clause is O(v). Where v is the number of variables appearing in the formula. This is true because on each clause, a variable can appear at most once, being on either a positive or negative literal. Otherwise, the formula could be further reduced. Therefore, k is O(v).

Biggest\_Clause\_Size is O(c), where c is the number of clauses in  $\Phi$ , since it needs to iterate through all clauses in  $\Phi$ . We use a similar argument to discuss that Clauses\_With\_Size is also O(c). Finally, occurrences (c, x) is O(v) because it is bounded on the size of the clause c. Therefore, the overall asymptotic complexity of DLIS is  $O(vc + v^3c) = O(v^3c)$ 

### 4.2. MCL

MCL consists of determining whether a variable has a greater number of positive occurrences then negative ones, while giving more weight to occurrences that appear at the smallest clauses. The reason for this is to solve the smallest clauses first, since they have more restrictions. The main goal of this heuristic is to find the adequate value to attribute the variable chosen by DLIS. We want to assign True to variables which have a greater weighted sum of positive occurrences and False otherwise.

The pseudocode of MCL is seen at Algorithm 4. Each clause size is O(v). Therefore, it is easy to see that the overall complexity of MCL is O(vc).

# **Algorithm 4 MCL**

```
Input: \Phi a clause set and a variable x
Output: Whether we assign True or False to x.
function MCL(\Phi, x)
    sum\_pos \leftarrow 0
    sum\_neg \leftarrow 0
    for Clause c in \Phi.Clauses do
         for Literal l in c do
             if l = x then
                 sum_pos \leftarrow sum_pos +\frac{1}{c.\text{Size}}
             else if l = \neg x then
                 sum\_neg \leftarrow sum\_neg + \frac{1}{c.Size}
             end if
         end for
    end for
      return sum_pos ≥ sum_neg
end function
```

# 4.3. Total complexity analysis

CIDPLL will make at most v recursive calls, one for each variable. Each recursive call is bounded by the complexity of <code>next\_variable</code> and <code>best\_value</code> heuristics. In this case, we have <code>DLIS</code> and <code>MCL</code>, with asymptotic complexity of  $O(v^3c)$  and O(vc), respectivly. Therefore, the total asymptotic complexity of our implementation of <code>CIDPLL</code> is  $O(v(v^3c+vc)) = O(v^4c)$ .

## 5. Experiment description and results

The experiments where run on a machine with the following specifications:

- System type: 64x
- Processor: Intel(R) Core(TM) i7-8750H CPU @2.20GHz 2.21GHz
- Memory: 16GB
- OS: Windows10, Version: 22H2
- Language: C++ version 11 compiled with g++ version 8.1.0.

For this report, we utilized the SATLIB - Benchmark Problems database of instances of the SAT problem [Hoos and Stützle 2024]. The scope was limited for 1000 samples, each one with 20 variables and 91 clauses, all satisfiable. These samples, containing boolean expressions in the conjunctive normal form, were stored in .cnf files.

The experiments consisted in reading the contents of each file and applying CIDPLL to the expressions they stored. In this, the algorithm had a success rate of 20.8%, measured by the percentage of expressions labeled as satisfiable, and a average execution time of 0.007344 seconds (with 6 decimal places of precision).

The code and the test instances are stored in the work's GitHub repository [Gabriel and Eduardo 2024].

The table with each individual result can be found below, where:

- name: the name of the test file;
- is\_sat\_result: the output of the algorithm (boolean);
- **is\_sat**: whether the solution (string) satisfies the expression;
- **time**: the time it took for CIDPLL to execute in seconds.

#### 6. Result discussion

The algorithm performed quite well with respect to the running time, but poorly in result correctness, considering that the test cases utilized were rather simple.

We speculate this lack of accuracy is due to the nature of the algorithm's approach at searching the space of all solutions. The algorithm cannot ensure that the choice it makes will yield to a solution. Additionally, the absence of a solution in the branch the algorithm traverses does not imply the absence of a global solution. Although the algorithm takes an educated guess on which value a variable must have, it doesn't guarantee a correct solution. Therefore, this can possibly doom the algorithm's chance at finding a satisfiable solution in its first choices.

#### 7. Conclusion

In this work, we presented a heuristic for solving the SAT problem. The heuristic is an adaptation of DPLL, aiming to improve the asymptotic complexity of the algorithm. The algorithm had a low success rate at finding a solution, but had a high performance in time. Therefore, the heuristic can be useful in contexts where a fast answer is needed with low requirements for accuracy.

For our future works, we plan to implement an exact algorithm and a meta heuristic for the SAT problem, as a continuation of the assignments proposed by the Algorithms Analysis and Projects discipline.
